Complex Numbers

This presentation contains some useful methods for solving problems involving complex numbers. Before going through the presentation make sure that you're familiar with the basic concepts, such as:

- Complex numbers arithmetic in Cartesian form.
- Argand diagram.
- Conversion between Cartesian and polar forms.
- Finding complex solutions to polynomials, including the use of Conjugate Root Theorem.
- Solving simultaneous equations with complex coefficients.
- De Moivre's Theorem.
- Multiplying and dividing complex numbers in polar form.
- Complex roots of unity and roots of complex numbers.

Complex numbers and vectors

- 2 Complex numbers and polynomials
- Complex numbers and trigonometry
- 4 Adding complex numbers in polar form

Some question on the exam papers are worded so that they seem as complex number question, but in fact can be done using vectors alone.

4 / 33

Question 1

Consider complex numbers: $z_1 = 2 + i$, $z_2 = -1 + 3i$ and $z_3 = 4 + 4i$. Show that the triangle in the complex plane with vertices in points represented by z_1, z_2 and z_3 is a right triangle.

Let the points A, B and C represent the complex numbers z_1 , z_2 and z_3 respectively.

6 / 33

Let the points A, B and C represent the complex numbers z_1, z_2 and z_3 respectively. Then $\overrightarrow{AB} = \begin{pmatrix} -3 \\ 2 \end{pmatrix}$ and $\overrightarrow{AC} = \begin{pmatrix} 2 \\ 3 \end{pmatrix}$.

Let the points A, B and C represent the complex numbers z_1 , z_2 and z_3 respectively. Then $\overrightarrow{AB} = \begin{pmatrix} -3 \\ 2 \end{pmatrix}$ and $\overrightarrow{AC} = \begin{pmatrix} 2 \\ 3 \end{pmatrix}$. So we have:

$$\overrightarrow{AB} \cdot \overrightarrow{AC} = \begin{pmatrix} -3 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} 2 \\ 3 \end{pmatrix} = -6 + 6 = 0$$

Let the points A, B and C represent the complex numbers z_1 , z_2 and z_3 respectively. Then $\overrightarrow{AB} = \begin{pmatrix} -3 \\ 2 \end{pmatrix}$ and $\overrightarrow{AC} = \begin{pmatrix} 2 \\ 3 \end{pmatrix}$. So we have:

$$\overrightarrow{AB} \cdot \overrightarrow{AC} = \begin{pmatrix} -3 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} 2 \\ 3 \end{pmatrix} = -6 + 6 = 0$$

Therefore $\angle BAC = 90^{\circ}$, what was to be proven.

Question 2

Points A, B and C on the complex plane represent the complex numbers -1 - i, 4 and 5 + 4i respectively. If ABCD is a parallelogram:

- a) find the complex number represented by point D, and
- b) find the acute angle between the diagonals of this parallelogram.

a) We have
$$\overrightarrow{OA} = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$$
, $\overrightarrow{OB} = \begin{pmatrix} 4 \\ 0 \end{pmatrix}$ and $\overrightarrow{OC} = \begin{pmatrix} 5 \\ 4 \end{pmatrix}$.

a) We have $\overrightarrow{OA} = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$, $\overrightarrow{OB} = \begin{pmatrix} 4 \\ 0 \end{pmatrix}$ and $\overrightarrow{OC} = \begin{pmatrix} 5 \\ 4 \end{pmatrix}$. If ABCD is a parallelogram, then $\overrightarrow{BA} = \overrightarrow{CD}$.

a) We have $\overrightarrow{OA} = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$, $\overrightarrow{OB} = \begin{pmatrix} 4 \\ 0 \end{pmatrix}$ and $\overrightarrow{OC} = \begin{pmatrix} 5 \\ 4 \end{pmatrix}$. If ABCD is a parallelogram, then $\overrightarrow{BA} = \overrightarrow{CD}$. So:

$$\overrightarrow{OD} = \overrightarrow{OC} + \overrightarrow{CD} = \overrightarrow{OC} + \overrightarrow{BA} = \begin{pmatrix} 5\\4 \end{pmatrix} + \begin{pmatrix} -5\\-1 \end{pmatrix} = \begin{pmatrix} 0\\3 \end{pmatrix}$$

a) We have $\overrightarrow{OA} = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$, $\overrightarrow{OB} = \begin{pmatrix} 4 \\ 0 \end{pmatrix}$ and $\overrightarrow{OC} = \begin{pmatrix} 5 \\ 4 \end{pmatrix}$. If \overrightarrow{ABCD} is a parallelogram, then $\overrightarrow{BA} = \overrightarrow{CD}$. So:

$$\overrightarrow{OD} = \overrightarrow{OC} + \overrightarrow{CD} = \overrightarrow{OC} + \overrightarrow{BA} = \begin{pmatrix} 5 \\ 4 \end{pmatrix} + \begin{pmatrix} -5 \\ -1 \end{pmatrix} = \begin{pmatrix} 0 \\ 3 \end{pmatrix}$$

So the point D represents the complex number 3i.

8 / 33

a) We have $\overrightarrow{OA} = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$, $\overrightarrow{OB} = \begin{pmatrix} 4 \\ 0 \end{pmatrix}$ and $\overrightarrow{OC} = \begin{pmatrix} 5 \\ 4 \end{pmatrix}$. If \overrightarrow{ABCD} is a parallelogram, then $\overrightarrow{BA} = \overrightarrow{CD}$. So:

$$\overrightarrow{OD} = \overrightarrow{OC} + \overrightarrow{CD} = \overrightarrow{OC} + \overrightarrow{BA} = \begin{pmatrix} 5 \\ 4 \end{pmatrix} + \begin{pmatrix} -5 \\ -1 \end{pmatrix} = \begin{pmatrix} 0 \\ 3 \end{pmatrix}$$

So the point D represents the complex number 3i.

b) We need to find the angle between the vectors \overrightarrow{AC} and \overrightarrow{DB} .

a) We have $\overrightarrow{OA} = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$, $\overrightarrow{OB} = \begin{pmatrix} 4 \\ 0 \end{pmatrix}$ and $\overrightarrow{OC} = \begin{pmatrix} 5 \\ 4 \end{pmatrix}$. If ABCD is a parallelogram, then $\overrightarrow{BA} = \overrightarrow{CD}$. So:

$$\overrightarrow{OD} = \overrightarrow{OC} + \overrightarrow{CD} = \overrightarrow{OC} + \overrightarrow{BA} = \begin{pmatrix} 5 \\ 4 \end{pmatrix} + \begin{pmatrix} -5 \\ -1 \end{pmatrix} = \begin{pmatrix} 0 \\ 3 \end{pmatrix}$$

So the point D represents the complex number 3i.

b) We need to find the angle between the vectors \overrightarrow{AC} and \overrightarrow{DB} .

$$\alpha = \arccos \frac{\overrightarrow{AC} \cdot \overrightarrow{DB}}{|\overrightarrow{AC}||\overrightarrow{DB}|} = \arccos \frac{9}{\sqrt{61}\sqrt{25}} = 76.7^{\circ}$$

- Complex numbers and vectors
- Complex numbers and polynomials
- Complex numbers and trigonometry
- 4 Adding complex numbers in polar form

Recall that given a polynomial:

$$P(x) = a_n x^n + a_{n-1} x^{n-1} + a_{n-2} x^{n-2} + \dots + a_1 x + a_0$$

with roots $x_1, x_2, x_3, ...x_n$. We have:

$$x_1 \cdot x_2 \cdot x_3 \cdot \dots \cdot x_n = (-1)^n \frac{a_0}{a_n}$$

and

$$x_1 + x_2 + x_3 + \dots + x_n = -\frac{a_{n-1}}{a_n}$$

Recall that given a polynomial:

$$P(x) = a_n x^n + a_{n-1} x^{n-1} + a_{n-2} x^{n-2} + \dots + a_1 x + a_0$$

with roots $x_1, x_2, x_3, ...x_n$. We have:

$$x_1 \cdot x_2 \cdot x_3 \cdot \dots \cdot x_n = (-1)^n \frac{a_0}{a_n}$$

and

$$x_1 + x_2 + x_3 + \dots + x_n = -\frac{a_{n-1}}{a_n}$$

These equations are of course also true if we work with complex roots of polynomials.

Question 3

Find the fifth roots of i and find their product.

We want to solve the equation

$$z^{5} = i$$

which is equivalent to

$$z^5 = cis\left(\frac{\pi}{2}\right)$$

We want to solve the equation

$$z^5 = i$$

which is equivalent to

$$z^5 = cis\left(\frac{\pi}{2}\right)$$

The roots are $z_k=cis\Big(rac{rac{\pi}{2}+2\pi k}{5}\Big)$ for k=0,1,2,3,4.

We want to solve the equation

$$z^{5} = i$$

which is equivalent to

$$z^5 = cis\left(\frac{\pi}{2}\right)$$

The roots are $z_k=cis\Big(rac{rac{\pi}{2}+2\pi k}{5}\Big)$ for k=0,1,2,3,4.

So we have:

$$z_0 = cis\left(rac{\pi}{10}
ight)$$
 $z_1 = cis\left(rac{\pi}{2}
ight)$ $z_2 = cis\left(rac{9\pi}{10}
ight)$ $z_3 = cis\left(rac{13\pi}{10}
ight)$ $z_4 = cis\left(rac{17\pi}{10}
ight)$

We can rewrite the original equation as:

$$z^5-i=0$$

We can rewrite the original equation as:

$$z^5-i=0$$

We want to find the product of the roots, which is equal to $(-1)^n \frac{a_0}{a_n}$

We can rewrite the original equation as:

$$z^5 - i = 0$$

We want to find the product of the roots, which is equal to $(-1)^n \frac{a_0}{a_n}$

In our case n = 5, $a_0 = -i$ and $a_n = 1$.

So we get:

$$z_0 \cdot z_1 \cdot z_2 \cdot z_3 \cdot z_4 = (-1)^5 \cdot \frac{-i}{1} = i$$

Question 4

Solve the equation $x^6 - 2x^3 + 4 = 0$ and hence show that:

$$\cos\frac{\pi}{9} + \cos\frac{7\pi}{9} + \cos\frac{13\pi}{9} = 0$$

We will use the substitution $u = x^3$, the equation then becomes:

$$u^2-2u+4=0$$

We will use the substitution $u = x^3$, the equation then becomes:

$$u^2 - 2u + 4 = 0$$
 We have $u = \frac{2 \pm \sqrt{4 - 16}}{2} = \frac{2 \pm 2i\sqrt{3}}{2} = 1 \pm i\sqrt{3}$. So we get:
$$u_1 = 1 + i\sqrt{3} \qquad \qquad u_2 = 1 - i\sqrt{3}$$

$$x^3 = 1 + i\sqrt{3} \qquad \text{or} \qquad x^3 = 1 - i\sqrt{3}$$

We will use the substitution $u = x^3$, the equation then becomes:

$$u^{2} - 2u + 4 = 0$$
We have $u = \frac{2 \pm \sqrt{4 - 16}}{2} = \frac{2 \pm 2i\sqrt{3}}{2} = 1 \pm i\sqrt{3}$. So we get:
$$u_{1} = 1 + i\sqrt{3}$$

$$u_{2} = 1 - i\sqrt{3}$$

$$u_1 = 1 + i\sqrt{3}$$
 $u_2 = 1 - i\sqrt{3}$
 $x^3 = 1 + i\sqrt{3}$ or $x^3 = 1 - i\sqrt{3}$

We will first solve $x^3 = 1 + i\sqrt{3} = 2cis\frac{\pi}{3}$.

We will use the substitution $u = x^3$, the equation then becomes:

$$u^2 - 2u + 4 = 0$$

We have $u = \frac{2 \pm \sqrt{4 - 16}}{2} = \frac{2 \pm 2i\sqrt{3}}{2} = 1 \pm i\sqrt{3}$. So we get:

$$u_1 = 1 + i\sqrt{3}$$
 $u_2 = 1 - i\sqrt{3}$
 $x^3 = 1 + i\sqrt{3}$ or $x^3 = 1 - i\sqrt{3}$

$$x^3 = 1 + i\sqrt{3}$$
 or $x^3 = 1 - i\sqrt{3}$

We will first solve $x^3 = 1 + i\sqrt{3} = 2cis\frac{\pi}{3}$.

We get:
$$x_k = \sqrt[3]{2} cis\left(\frac{\frac{\pi}{3} + 2\pi k}{3}\right)$$
 for $k = 0, 1, 2$.

So we have:

$$x_0 = \sqrt[3]{2} cis(\tfrac{\pi}{9})$$

$$x_1 = \sqrt[3]{2} cis(\frac{7\pi}{9})$$

$$x_2 = \sqrt[3]{2} cis\left(\frac{13\pi}{9}\right)$$

So we have:

$$x_0 = \sqrt[3]{2}cis(\frac{\pi}{9})$$
 $x_1 = \sqrt[3]{2}cis(\frac{7\pi}{9})$ $x_2 = \sqrt[3]{2}cis(\frac{13\pi}{9})$

Note that these do not come in conjugate pairs. The original polynomial has degree 6, so there should be 3 more solutions, and these will be the conjugates of the above (so there is no need to solve $x^3 = 1 - i\sqrt{3}$)

So we have:

$$x_0 = \sqrt[3]{2} cis(\frac{\pi}{9})$$
 $x_1 = \sqrt[3]{2} cis(\frac{7\pi}{9})$ $x_2 = \sqrt[3]{2} cis(\frac{13\pi}{9})$

Note that these do not come in conjugate pairs. The original polynomial has degree 6, so there should be 3 more solutions, and these will be the conjugates of the above (so there is no need to solve $x^3 = 1 - i\sqrt{3}$)

$$x_4 = \sqrt[3]{2}cis(-\frac{\pi}{9})$$
 $x_5 = \sqrt[3]{2}cis(-\frac{7\pi}{9})$ $x_6 = \sqrt[3]{2}cis(-\frac{13\pi}{9})$

The sum of the roots of the polynomial is 0. Consider the real part of this sum (of course it is also 0). Using the fact that cos is an even function, we get:

$$Re(\sum_{i} x_{i}) = 2\sqrt[3]{2}\cos\left(\frac{\pi}{9}\right) + 2\sqrt[3]{2}\cos\left(\frac{7\pi}{9}\right) + 2\sqrt[3]{2}\cos\left(\frac{13\pi}{9}\right) = 0$$

The sum of the roots of the polynomial is 0. Consider the real part of this sum (of course it is also 0). Using the fact that cos is an even function, we get:

$$Re(\sum_{i} x_{i}) = 2\sqrt[3]{2}\cos\left(\frac{\pi}{9}\right) + 2\sqrt[3]{2}\cos\left(\frac{7\pi}{9}\right) + 2\sqrt[3]{2}\cos\left(\frac{13\pi}{9}\right) = 0$$

which gives:

$$\cos\!\left(\frac{\pi}{9}\right) + \cos\!\left(\frac{7\pi}{9}\right) + \cos\!\left(\frac{13\pi}{9}\right) = 0$$

Complex numbers and vectors

- Complex numbers and polynomials
- Complex numbers and trigonometry
- 4 Adding complex numbers in polar form

• $\cos^n \theta = \dots$

• $\cos^n \theta = \dots$ Here we use the fact that if $z = cis\theta$, then $z + \frac{1}{z} = 2\cos\theta$.

- $\cos^n \theta = \dots$ Here we use the fact that if $z = cis\theta$, then $z + \frac{1}{z} = 2\cos\theta$.
- $\cos n\theta = \dots$

- $\cos^n \theta = \dots$ Here we use the fact that if $z = cis\theta$, then $z + \frac{1}{z} = 2\cos\theta$.
- $\cos n\theta = ...$ Here we use the fact that $\cos n\theta = Re(cis^n\theta)$

- $\cos^n \theta = \dots$ Here we use the fact that if $z = cis\theta$, then $z + \frac{1}{z} = 2\cos\theta$.
- $\cos n\theta = ...$ Here we use the fact that $\cos n\theta = Re(cis^n\theta)$

Of course you may be asked to prove identities for any trigonometric function, similar approaches are then used.

Question 5

Prove that

$$\cos^6 \theta = \frac{1}{32} \cos 6\theta + \frac{3}{16} \cos 4\theta + \frac{15}{32} \cos 2\theta + \frac{5}{16}$$

Let $z = cis\theta$. Then

$$(2\cos\theta)^6 = \left(z + \frac{1}{z}\right)^6 =$$

$$= z^6 + 6z^4 + 15z^2 + 20 + \frac{15}{z^2} + \frac{6}{z^4} + \frac{1}{z^6} =$$

$$= \left(z^6 + \frac{1}{z^6}\right) + 6\left(z^4 + \frac{1}{z^4}\right) + 15\left(z^2 + \frac{1}{z^2}\right) + 20 =$$

$$= 2\cos 6\theta + 6 \cdot 2\cos 4\theta + 15 \cdot 2\cos 2\theta + 20$$

We get that:

$$64\cos^6\theta = 2\cos 6\theta + 12\cos 4\theta + 30\cos 2\theta + 20$$

We get that:

$$64\cos^6\theta = 2\cos 6\theta + 12\cos 4\theta + 30\cos 2\theta + 20$$

Dividing both sides by 64 we get the desired result: Prove that

$$\cos^6 \theta = \frac{1}{32} \cos 6\theta + \frac{3}{16} \cos 4\theta + \frac{15}{32} \cos 2\theta + \frac{5}{16}$$

Question 6

Express $\sin 5\theta$ in terms of $\sin \theta$.

$$\sin 5\theta = Im(cis^5\theta) =$$

$$= Im(\cos^5\theta + 5i\cos^4\theta\sin\theta + 10i^2\cos^3\theta\sin^2\theta +$$

$$+ 10i^3\cos^2\theta\sin^3\theta + 5i^4\cos\theta\sin^4\theta + i^5\sin^5\theta) =$$

$$= 5\cos^4\theta\sin\theta - 10\cos^2\sin^3\theta + \sin^5\theta$$

$$\sin 5\theta = Im(cis^5\theta) =$$

$$= Im(\cos^5\theta + 5i\cos^4\theta\sin\theta + 10i^2\cos^3\theta\sin^2\theta +$$

$$+ 10i^3\cos^2\theta\sin^3\theta + 5i^4\cos\theta\sin^6\theta + i^5\sin^5\theta) =$$

$$= 5\cos^4\theta\sin\theta - 10\cos^2\sin^3\theta + \sin^5\theta$$

Now we use the identity $\cos^2\theta=1-\sin^2\theta$ to replace cosines with sines and we get:

$$\sin 5\theta = 5(1 - \sin^2 \theta)^2 \sin \theta - 10(1 - \sin^2 \theta) \sin^3 \theta + \sin^5 \theta$$

= $16 \sin^5 \theta - 20 \sin^3 \theta + 5 \sin \theta$

- Complex numbers and vectors
- 2 Complex numbers and polynomials
- Complex numbers and trigonometry
- Adding complex numbers in polar form

There is a useful method for adding or subtracting two complex numbers with the same modulus. This is particularly handy if one of the complex numbers is expressed in terms of a variable.

There is a useful method for adding or subtracting two complex numbers with the same modulus. This is particularly handy if one of the complex numbers is expressed in terms of a variable.

The method rests on the following identities (also used for proving trig identities):

$$cis(\theta) + cis(-\theta) = 2\cos\theta$$

$$cis(\theta) - cis(-\theta) = 2i \sin \theta$$

Question 7

Express in terms of $\boldsymbol{\theta}$ the modulus and argument of

$$z = i + \cos \theta - i \sin \theta$$

for
$$\theta \in [-\frac{3\pi}{2}, \frac{\pi}{2}]$$
.

We are adding two complex numbers here, one i in the Cartesian form, the other is almost in polar form (we need to get rid of the minus in front of the sine).

We are adding two complex numbers here, one i in the Cartesian form, the other is almost in polar form (we need to get rid of the minus in front of the sine).

We will express both numbers in the polar form:

$$i + \cos \theta - i \sin \theta = cis(\frac{\pi}{2}) + cis(-\theta)$$

We are adding two complex numbers here, one i in the Cartesian form, the other is almost in polar form (we need to get rid of the minus in front of the sine).

We will express both numbers in the polar form:

$$i + \cos \theta - i \sin \theta = cis(\frac{\pi}{2}) + cis(-\theta)$$

Now we will factor out the complex number whose argument is the average of the two arguments (in our case $\frac{\pi}{4} - \frac{\theta}{2}$) and whose modulus is the same as that of the added numbers (in our case 1).

We get:

$$i + \cos \theta - i \sin \theta = cis\left(\frac{\pi}{2}\right) + cis(-\theta) =$$

$$= cis\left(\frac{\pi}{4} - \frac{\theta}{2}\right)\left(cis\left(\frac{\pi}{4} + \frac{\theta}{2}\right) + cis\left(-\frac{\pi}{4} - \frac{\theta}{2}\right)\right) =$$

$$= cis\left(\frac{\pi}{4} - \frac{\theta}{2}\right)2\cos\left(\frac{\pi}{4} + \frac{\theta}{2}\right)$$

We get:

$$i + \cos \theta - i \sin \theta = cis\left(\frac{\pi}{2}\right) + cis(-\theta) =$$

$$= cis\left(\frac{\pi}{4} - \frac{\theta}{2}\right)\left(cis\left(\frac{\pi}{4} + \frac{\theta}{2}\right) + cis\left(-\frac{\pi}{4} - \frac{\theta}{2}\right)\right) =$$

$$= cis\left(\frac{\pi}{4} - \frac{\theta}{2}\right)2\cos\left(\frac{\pi}{4} + \frac{\theta}{2}\right)$$

So our complex number $z=2\cos\left(\frac{\pi}{4}+\frac{\theta}{2}\right)cis\left(\frac{\pi}{4}-\frac{\theta}{2}\right)$. Now we can just read off the modulus and argument:

$$|z| = 2\cos\left(\frac{\pi}{4} + \frac{\theta}{2}\right)$$
 $arg(z) = \frac{\pi}{4} - \frac{\theta}{2}$

Question 8

Express in terms of $\boldsymbol{\theta}$ the modulus and argument of

$$z = i - \cos \theta - i \sin \theta$$

for
$$\theta \in \left[\frac{\pi}{2}, \frac{5\pi}{2}\right]$$

We will use a similar approach.

$$i - \cos \theta - i \sin \theta = cis\left(\frac{\pi}{2}\right) - cis(\theta) =$$

$$= cis\left(\frac{\pi}{4} + \frac{\theta}{2}\right)\left(cis\left(\frac{\pi}{4} - \frac{\theta}{2}\right) - cis\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)\right) =$$

$$= cis\left(\frac{\pi}{4} + \frac{\theta}{2}\right)\left(-2i\sin\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)\right)$$

We will use a similar approach.

$$i - \cos \theta - i \sin \theta = cis\left(\frac{\pi}{2}\right) - cis(\theta) =$$

$$= cis\left(\frac{\pi}{4} + \frac{\theta}{2}\right)\left(cis\left(\frac{\pi}{4} - \frac{\theta}{2}\right) - cis\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)\right) =$$

$$= cis\left(\frac{\pi}{4} + \frac{\theta}{2}\right)\left(-2i\sin\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)\right)$$

Now we need to convert -i into the polar form:

$$\operatorname{cis}\left(\frac{\pi}{4} + \frac{\theta}{2}\right)\left(-2i\sin\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)\right) = 2\sin\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)\operatorname{cis}\left(-\frac{\pi}{2}\right)\operatorname{cis}\left(\frac{\pi}{4} + \frac{\theta}{2}\right)$$

 Comasz Lechowski
 Batory AA HL
 January 27, 2023
 31 / 33

Finally we get:

$$z=2\sin\left(-\frac{\pi}{4}+\frac{\theta}{2}\right)cis\left(-\frac{\pi}{2}\right)cis\left(\frac{\pi}{4}+\frac{\theta}{2}\right)=2\sin\left(-\frac{\pi}{4}+\frac{\theta}{2}\right)cis\left(-\frac{\pi}{4}+\frac{\theta}{2}\right)$$

Tomasz Lechowski

Finally we get:

$$z = 2\sin\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)cis\left(-\frac{\pi}{2}\right)cis\left(\frac{\pi}{4} + \frac{\theta}{2}\right) = 2\sin\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)cis\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)$$

So:

$$|z| = 2\sin\left(-\frac{\pi}{4} + \frac{\theta}{2}\right)$$
 $arg(z) = -\frac{\pi}{4} + \frac{\theta}{2}$

Questions 7, 8 - final remarks

In these kinds of questions you need to be very careful about the signs.

As an example consider a complex number $z = \cos(\frac{3\pi}{4})cis(\frac{\pi}{4})$. What is its argument?

Questions 7, 8 - final remarks

In these kinds of questions you need to be very careful about the signs.

As an example consider a complex number $z = \cos(\frac{3\pi}{4})cis(\frac{\pi}{4})$. What is its argument?

You may think that it is $\frac{\pi}{4}$, but this is not the case since $\cos(\frac{3\pi}{4})$ is negative, so we in fact have:

$$z = \cos\left(\frac{3\pi}{4}\right)cis\left(\frac{\pi}{4}\right) = -\cos\left(\frac{-\pi}{4}\right)cis\left(\frac{\pi}{4}\right) =$$
$$= cis(\pi)\cos\left(\frac{-\pi}{4}\right)cis\left(\frac{\pi}{4}\right) = \cos\left(\frac{\pi}{4}\right)cis\left(\frac{5\pi}{4}\right)$$

Questions 7, 8 - final remarks

In these kinds of questions you need to be very careful about the signs.

As an example consider a complex number $z = \cos(\frac{3\pi}{4})cis(\frac{\pi}{4})$. What is its argument?

You may think that it is $\frac{\pi}{4}$, but this is not the case since $\cos(\frac{3\pi}{4})$ is negative, so we in fact have:

$$z = \cos\left(\frac{3\pi}{4}\right)cis\left(\frac{\pi}{4}\right) = -\cos\left(\frac{-\pi}{4}\right)cis\left(\frac{\pi}{4}\right) =$$
$$= cis(\pi)\cos\left(\frac{-\pi}{4}\right)cis\left(\frac{\pi}{4}\right) = \cos\left(\frac{\pi}{4}\right)cis\left(\frac{5\pi}{4}\right)$$

So
$$arg(z) = \frac{5\pi}{4}$$
.
